Heritage Rank Status Factors

Elcode NFSM000118

Gname PHAEOCOLLYBIA CALIFORNICA

Gcomname

Number of Occurrences

B = 6 - 20

Comments

The ISMS 2002 database erroneously cites 44 P. californica occurrences in the northern spotted owl region. When the current author evaluated herbarium collections, she accepted the synonymy of P. scatesiae with P. californica proposed in 1977. After formal recognition of two separate species in 1998, Norvell notified the Regional Mycology Lab regarding the change in taxonomic status, but correction to the existing database appears incomplete. Of the original 17 P. californica occurrences submitted, only 8 (none believed extant), represent P californica. The 2002 ISMS database and P. californica map includes 5 original P. scatesiae sites. Due to this confusion as well as the presumed difficulty in nonexperts distinguishing between the two species, only 18 occurrences (7 extant) verified by this author, are cited here. Other Survey and Manage collections made from habitats containing Quercus, however, are also likely to represent P. californica. Unfortunately those habitat data are not available to this author (Norvell 1995, 1998ab, pers. comm. 2002).

Number of Occurrences with Good Viability

C = Few (4-12) occurrences with good viability

Comments

Due to taxonomic confusion between P. californica and P. scatesiae in the ISMS database, only 7 occurrences can be recognized as extant. Although the fungus is very rare, it is likely that more occurrences are in Oregon and California where Quercus is found.

Population Size

U = Unknown

Comments

Records reflect only species occurrence, i.e. fruitbodies, not numbers of individuals. Genets of ectomycorrhizal fungi cannot be delimited without DNA sampling.

Range Extent

F = 20,000-200,000 km 2 (about 8,000-80,000 square miles)

Comments

Endemic to the northern spotted region in western North America and known only in coastal and coast range locations in Oregon from Cape Meares south to Jedediah Smith State Park and east to Castle Crags State Park in California, The ISMS 2002 Phaeocollybia californica map shows two species: P. californica and P. scatesiae. From 1977 until 1998, the two species were considered synonymous.

Area of Occupancy

U = Unknown

LU = Unknown

Comments

Occupancy is highly spotty and cannot be extrapolated for this organism, which appears restricted to fairly complex environments. For fungi one can only estimate the area of occupancy from fruitbodies as the vegetative organism is underground had has unknown biological and ecological

requirements that determine how and when ectomycorrhizal associations are formed with coniferous host trees. The fungus fruits sporadically (not annually) and produces many small scattered fruitbodies.

Long-term Trend in Population Size, Extent of Occurrence, Area of Occupancy, and/or Number or Condition of Occurrences

B = Large Decline (decline of 75-90%)

C = Substantial Decline (decline of 50-75%)

D = Moderate Decline (decline of 25-50%)

Comments

Due to the spotty nature of the occurrences, it is difficult to project a long-term trend in population size, extent of occurrence, or the area of occupancy. Ectomycorrhizal fungal stability in general is tied to the stability of the coniferous partner trees. It would be fair to estimate a long-term trend in population size based on the forest trend. The species appears restricted to mature (i.e. 65 year old) to late-successional/old-growth forests that contain Quercus or (possibly) Lithocarpus. The recent rise in sudden oak death in California means that in that state the populations are greatly imperiled (Norvell 2002 pers comm).

Short-term Trend in Population Size, Extent of Occurrence, Area of Occupancy, and/or Number or Condition of Occurrences

C = Rapidly Declining. Decline of 30-50% in population, range, area occupied, and/or number or condition of occurrences

D = Declining. Decline of 10-30% in population, range, area occupied, and/or number or condition of occurrences

Comments

Ectomycorrhizal fungal stability in general is tied to the stability of the coniferous partner trees. It would be fair to estimate a short-term trend in population size based on the forest trend. In this instance, the presumed mycorrhizal association with fagaceous partners and the recent appearance of the sudden oak death Phytophthora infection places this species at risk (Norvell 2002 pers comm). A few questionable collections have been confirmed by this author; two were reported from strictly coniferous forests.

Threats

A = Substantial, imminent threat. Threat is moderate to severe and imminent for most (> 60%) of the population, occurrences, or area. Ecological community occurrences are directly impacted over a widespread area, either causing irreversible damage or requiring long term recovery

Scope High Severity High Immediacy Moderate

Comments

Ectomycorrhizal fungal stability depends on the stability of the symbiotic partners, so that what threatens extant forests threaten the organism. This species appears restricted to late-successional/old-growth mixed coniferous-fagaceous forests (Norvell 1998ab, Norvell pers. comm. 2002). It also appears to grow slowly. (Norvell 1998ab) Would be threatened by hot fires, development, and heavy logging activities. The most immediate and serious threat is the rise of the Phytophthora pathogen in California forests associated with "sudden oak death", the presumed preferred mycorrhizal partner of P. californica.

Number of Appropriately Protected and Managed Occurrences

C = Several (4-12) occurrences appropriately protected and managed

Comments

Of the 18 currently accepted occurrences, approximately 12 lie in forests that have not been logged or developed. Of those, 3 lie in permanently protected preserves and 2 in late-successional reserves. Of the 7 most recent (and thus accepted as extant) occurrences, two were collected in the McDonald and Paul Dunn Forests north of Corvallis and the other 5 were collected from unprotected lands.

Intrinsic Vulnerability

A = Highly Vulnerable. Species is slow to mature, reproduces infrequently, and/or has low fecundity such that populations are very slow (> 20 years or 5 generations) to recover from decreases in abundance; or species has low dispersal capability such that extirpated populations are unlikely to become reestablished through natural recolonization (unaided by humans). Ecological community occurrences are highly susceptible to changes in composition and structure that rarely if ever are reversed through natural processes even over substantial time periods (> 100 years).

B = Moderately Vulnerable. Species exhibits moderate age of maturity, frequency of reproduction, and/or fecundity such that populations generally tend to recover from decreases in abundance over a period of several years (on the order of 5-20 years or 2-5 generations); or species has moderate dispersal capability such that extirpated populations generally become reestablished through natural recolonization (unaided by humans). Ecological community occurrences may be susceptible to changes in composition and structure but tend to recover through natural processes given reasonable time (10-100 years).

Comments

Ectomycorrhizal fungal vulnerability generally is linked to that of the coniferous partner trees. P. californica is thought by this author (Norvell pers comm 2002) to associate preferentially with Quercus (Norvell 1998a, pers comm 2002). It is therefore vulnerable with its associate to hot fires, heavy logging (not moderate to light thinning), and the Phytophthora causing "sudden oak death" in California and southern Oregon, Norvell pers. Comm. 2002).

Environmental Specificity

B = Narrow. Specialist or community with key requirements common.

Comments

The species appears to prefer habitats in which Quercus (or possibly Lithocarpus) is present, although a few questionable collections have been made from strictly coniferous forests. Precise biological and ecological requirements beyond moist forests are unknown at this time. (Norvell 1998ab, pers comm 2002).

Other Considerations

NRANK - N2? The onset of sudden oak death in California and southern Oregon threatens the presumed preferred mycorrhizal partner. There is confusion in the ISMS 2002 database resulting from dissolution of the 1977-1998 synonymy of Phaeocollybia californica and Phaeocollybia scatesiae (Norvell1998a).

Edition 11/18/2002 Edauthor Lorelei L Norvell

Grank G2? **Grank Date** 11/18/2002

Greasons

Only 7 populations are confirmed as extant by this author, although more are likely to be determined from southern Oregon where Quercus is more common. There are only 5 currently protected occurrence sites, but 3 occurrences may no longer be extant. The species should be considered uncommon to rare and at risk. The most immediate threat is infection of its presumed preferred mycorrhizal partner by the Phytophthora species causing "sudden oak death" in California and southern Oregon. The populations are also at risk from hot fires, heavy logging or development. Total predicted occurrences may be ~30-40 and reinspection of recent collections may confirm some collections in the ISMS database as representing Phaeocollybia californica. The spotty distribution and unpredictable phenology common to all phaeocollybias complicate ranking this organism.
